Chapter 17
Basic Numerical Methods

This chapter is an elementary introduction to finite difference methods for the resolution of PDEs and stochastic differential equations. We cover the explicit and implicit finite difference schemes for the heat equations and the Black-Scholes PDE, as well as the Euler and Milstein schemes for stochastic differential equations.

17.1 Discretized Heat Equation ...................... 621
17.2 Discretized Black-Scholes PDE .................. 624
17.3 Euler Discretization ............................ 628
17.4 Milstein Discretization ........................ 629

17.1 Discretized Heat Equation

Consider the heat equation

\[ \frac{\partial \phi}{\partial t}(t, x) = \frac{\partial^2 \phi}{\partial x^2}(t, x) \]  \hspace{1cm} (17.1)

with initial condition

\[ \phi(0, x) = f(x) \]

on a compact time-space interval \([0, T] \times [0, X]\).

The intervals \([0, T]\) and \([0, X]\) are respectively discretized according to \(\{t_0 = 0, t_1, \ldots, t_N = T\}\) and \(\{x_0 = 0, t_1, \ldots, t_M = X\}\) with \(\Delta t = T/N\) and \(\Delta x = X/M\), from which we construct a grid

\[ (t_i, x_j) = (i\Delta t, j\Delta x), \quad i = 0, \ldots, N, \quad j = 0, \ldots, M, \]

on \([0, T] \times [0, X]\).
Our goal is to solve the heat equation \(17.1\) with \textit{initial} condition \(\phi(0, x)\) and lateral boundary conditions \(\phi(t, 0), \phi(t, X)\), via a discrete approximation of the solution to \(17.1\), by evaluating derivatives using finite differences.

**Explicit scheme**

Using the \textit{forward} time difference approximation

\[
\frac{\partial \phi}{\partial t}(t, x) \simeq \frac{\phi(t_{i+1}, x_j) - \phi(t_i, x_j)}{\Delta t}
\]

of the time derivative, and the related space difference approximations

\[
\frac{\partial \phi}{\partial x}(t, x_j) \simeq \frac{\phi(t, x_{j+1}) - \phi(t, x_j)}{\Delta x}, \quad \frac{\partial \phi}{\partial x}(t, x_{j+1}) \simeq \frac{\phi(t, x_{j+1}) - \phi(t, x_j)}{\Delta x}
\]

and

\[
\frac{\partial^2 \phi}{\partial x^2}(t, x_j) \simeq \frac{1}{\Delta x} \left( \frac{\partial \phi}{\partial x}(t, x_{j+1}) - \frac{\partial \phi}{\partial x}(t, x_j) \right) = \frac{\phi(t, x_{j+1}) + \phi(t, x_{j-1}) - 2\phi(t, x_j)}{(\Delta x)^2}
\]

of the time and space derivatives, we discretize \(17.1\) as

\[
\frac{\phi(t_{i+1}, x_j) - \phi(t_i, x_j)}{\Delta t} = \frac{\phi(t_i, x_{j+1}) + \phi(t_i, x_{j-1}) - 2\phi(t_i, x_j)}{(\Delta x)^2}. \tag{17.2}
\]

Letting \(\rho = (\Delta t)/(\Delta x)^2\), this yields

\[
\phi(t_{i+1}, x_j) = \rho \phi(t_i, x_{j+1}) + (1 - 2\rho) \phi(t_i, x_j) + \rho \phi(t_i, x_{j-1}),
\]

\(1 \leq j \leq M - 1, 1 \leq i \leq N\), \textit{i.e.}

\[
\Phi_{i+1} = A \Phi_i + \rho \begin{bmatrix} \phi(t_i, x_0) \\ 0 \\ \vdots \\ \phi(t_i, x_M) \end{bmatrix}, \quad i = 0, 1, \ldots, N - 1, \tag{17.3}
\]

with

\[
\Phi_i = \begin{bmatrix} \phi(t_i, x_1) \\ \vdots \\ \phi(t_i, x_M) \end{bmatrix}, \quad i = 0, 1, \ldots, N,
\]
Basic Numerical Methods

\[
A = \begin{bmatrix}
1 - 2\rho & \rho & 0 & \cdots & 0 & 0 & 0 \\
\rho & 1 - 2\rho & \rho & \cdots & 0 & 0 & 0 \\
0 & \rho & 1 - 2\rho & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & 1 - 2\rho & \rho & 0 \\
0 & 0 & 0 & \cdots & \rho & 1 - 2\rho & \rho \\
0 & 0 & 0 & \cdots & 0 & \rho & 1 - 2\rho
\end{bmatrix}
\]

The vector

\[
\begin{bmatrix}
\phi(t_i, x_0) \\
0 \\
\vdots \\
0 \\
\phi(t_i, x_M)
\end{bmatrix} = \begin{bmatrix}
\phi(t_i, 0) \\
0 \\
\vdots \\
0 \\
\phi(t_i, X)
\end{bmatrix}, \quad i = 0, 1, \ldots, N,
\]

in (17.3) can be given by the lateral boundary conditions \(\phi(t, 0)\) and \(\phi(t, X)\). From those boundary conditions and the initial data of

\[
\Phi_0 = \begin{bmatrix}
\phi(0, x_0) \\
\phi(0, x_1) \\
\vdots \\
\phi(0, x_{M-1}) \\
\phi(0, x_M)
\end{bmatrix}
\]

we can apply (17.3) in order to solve (17.2) recursively for \(\Phi_1, \Phi_2, \Phi_3, \ldots\)

**Implicit scheme**

Using the *backward* time difference approximation

\[
\frac{\partial \phi}{\partial t}(t_i, x) \simeq \frac{\phi(t_i, x_j) - \phi(t_{i-1}, x_j)}{\Delta t}
\]

of the time derivative, we discretize (17.1) as

\[
\frac{\phi(t_i, x_j) - \phi(t_{i-1}, x_j)}{\Delta t} = \frac{\phi(t_i, x_{j+1}) + \phi(t_i, x_{j-1}) - 2\phi(t_i, x_j)}{(\Delta x)^2}
\]

(17.4)

and letting \(\rho = (\Delta t)/(\Delta x)^2\) we get

\[
\phi(t_{i-1}, x_j) = -\rho\phi(t_i, x_{j+1}) + (1 + 2\rho)\phi(t_i, x_j) - \rho\phi(t_i, x_{j-1}),
\]

\(1 \leq j \leq M - 1, 1 \leq i \leq N, \text{ i.e.}\)
\[
\Phi_{i-1} = B \Phi_i + \rho \begin{bmatrix}
\phi(t_i, x_0) \\
0 \\
\vdots \\
0 \\
\phi(t_i, x_M)
\end{bmatrix}, \quad i = 1, 2, \ldots, N,
\]

with
\[
B = \begin{bmatrix}
1 + 2\rho & -\rho & 0 & \cdots & 0 & 0 & 0 \\
-\rho & 1 + 2\rho & -\rho & \cdots & 0 & 0 & 0 \\
0 & -\rho & 1 + 2\rho & \cdots & 0 & 0 & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & 0 & 0 & \cdots & 1 + 2\rho & -\rho & 0 \\
0 & 0 & 0 & \cdots & -\rho & 1 + 2\rho & -\rho \\
0 & 0 & 0 & \cdots & 0 & -\rho & 1 + 2\rho
\end{bmatrix}.
\]

By inversion of the matrix \(B\), \(\Phi_i\) is given in terms of \(\Phi_{i-1}\) as
\[
\Phi_i = B^{-1} \Phi_{i-1} - \rho B^{-1} \begin{bmatrix}
\phi(t_i, x_0) \\
0 \\
\vdots \\
0 \\
\phi(t_i, x_M)
\end{bmatrix}, \quad i = 1, \ldots, N,
\]

which also allows for a recursive solution of (17.4).

### 17.2 Discretized Black-Scholes PDE

Consider the Black-Scholes PDE
\[
r \phi(t, x) = \frac{\partial \phi}{\partial t}(t, x) + r x \frac{\partial \phi}{\partial x}(t, x) + \frac{1}{2} x^2 \sigma^2 \frac{\partial^2 \phi}{\partial x^2}(t, x),
\]

under the terminal condition \(\phi(T, x) = (x - K)^+\), resp. \(\phi(T, x) = (K - x)^+\), for a European call, resp. put, option. The constant volatility coefficient \(\sigma\) may also be replaced with a function \(\sigma(t, x)\) of the underlying, in the case local volatility models.

Note that in the solution of the Black-Scholes PDE, time is run backwards as we start from a terminal condition \(\phi(T, x)\) at time \(T\). Thus here the explicit scheme uses backward differences while the implicit scheme uses forward differences.
Basic Numerical Methods

Explicit scheme

Using here the backward time difference approximation

$$\frac{\partial \phi}{\partial t}(t_i, x) \simeq \frac{\phi(t_i, x_j) - \phi(t_{i-1}, x_j)}{\Delta t}$$

of the time derivative, we discretize (17.5) as

$$r \phi(t_i, x_j) = \frac{\phi(t_i, x_j) - \phi(t_{i-1}, x_j)}{\Delta t} + r x_j \frac{\phi(t_i, x_{j+1}) - \phi(t_i, x_{j-1})}{2\Delta x} + \frac{1}{2} x_j^2 \sigma^2 \frac{\phi(t_i, x_{j+1}) + \phi(t_i, x_{j-1}) - 2\phi(t_i, x_j)}{(\Delta x)^2}, \quad (17.6)$$

$$1 \leq j \leq M - 1, \quad 0 \leq i \leq N - 1, \quad i.e.$$

$$\phi(t_{i-1}, x_j) = \frac{1}{2} (\sigma^2 j^2 - r j) \phi(t_i, x_{j-1}) \Delta t + \phi(t_i, x_j) (1 - (\sigma^2 j^2 + r) \Delta t)$$

$$+ \frac{1}{2} (\sigma^2 j^2 + r j) \phi(t_i, x_{j+1}) \Delta t,$$

$$1 \leq j \leq M - 1,$$ where the lateral boundary conditions \( \phi(t_i, 0) \) and \( \phi(t_i, x_M) \)
are (approximately) given as follows.

European call options. We take

$$\phi(t_i, x_0) = 0, \quad and \quad \phi(t_i, x_M) \simeq (x_M - K e^{-r(T-t_i)})^+ = x_M - K e^{-r(T-t_i)},$$

\( i = 0, 1, \ldots, N, \) provided that \( x_M \) is sufficiently large.

European put options. We take

$$\phi(t_i, x_0) = (K e^{-r(T-t_i)} - x_0)^+ = K e^{-r(T-t_i)}, \quad \text{and} \quad \phi(t_i, x_M) = 0,$$

\( i = 0, 1, \ldots, N, \) with here \( x_0 = 0. \)

Given a terminal condition of the form

$$\phi(T, x_j) = (x_j - K)^+, \quad \text{resp.} \quad \phi(T, x_j) = (K - x_j)^+, \quad j = 1, \ldots, M - 1,$$

this allows us to solve (17.6) successively for

$$\phi(t_{N-1}, x_j), \ \phi(t_{N-2}, x_j), \ \phi(t_{N-3}, x_j), \ldots, \phi(t_1, x_{j}), \ \phi(t_0, x_j).$$

The explicit finite difference method is nevertheless known to have a divergent behaviour as time is run backwards, as illustrated in Figure 17.1.
F\textsuperscript{ig. 17.1: Divergence of the explicit finite difference method.}

**Implicit scheme**

Using the *forward* time difference approximation
\[
\frac{\partial \phi}{\partial t}(t_i, x) \approx \frac{\phi(t_{i+1}, x_j) - \phi(t_i, x_j)}{\Delta t}
\]
of the time derivative, we discretize (17.5) as
\[
r\phi(t_i, x_j) = \frac{\phi(t_{i+1}, x_j) - \phi(t_i, x_j)}{\Delta t} + r x_j \frac{\phi(t_i, x_{j+1}) - \phi(t_i, x_{j-1})}{\Delta x}
+ \frac{1}{2} x_j^2 \phi(t_i, x_{j+1}) + \phi(t_i, x_{j-1}) - 2\phi(t_i, x_j)
\]
\[
1 \leq j \leq M - 1, 0 \leq i \leq N - 1, \text{i.e.}
\]
\[
\phi(t_{i+1}, x_j) = -\frac{1}{2} \left( \sigma^2 j^2 - rj \right) \phi(t_i, x_{j-1}) \Delta t + \phi(t_i, x_j) \left( 1 + \left( \sigma^2 j^2 + r \right) \Delta t \right)
\]
\[
-\frac{1}{2} \left( \sigma^2 j^2 + rj \right) \phi(t_i, x_{j+1}) \Delta t,
\]
\[
1 \leq j \leq M - 1, \text{i.e.}
\]
\[
\Phi_{i+1} = B\Phi_i +
\begin{bmatrix}
\frac{1}{2} (r - \sigma^2) \phi(t_i, x_0) \Delta t \\
0 \\
\vdots \\
0 \\
-\frac{1}{2} \left( r(M-1) + \sigma^2 (M-1)^2 \right) \phi(t_i, x_M) \Delta t
\end{bmatrix},
\]
i = 0, 1, \ldots, N - 1, \text{with}

This version: March 18, 2019
http://www.ntu.edu.sg/home/nprivault/indext.html
Basic Numerical Methods

\[ B_{j,j-1} = \frac{1}{2} \left( r_j - \sigma^2 j^2 \right) \Delta t, \quad B_{j,j} = 1 + \sigma^2 j^2 \Delta t + r \Delta t, \]

and

\[ B_{j,j+1} = -\frac{1}{2} \left( r_j + \sigma^2 j^2 \right) \Delta t, \]

for \( j = 1, 2, \ldots, M - 1 \), and \( B(i,j) = 0 \) otherwise.

By inversion of the matrix \( B \), \( \Phi_i \) is given in terms of \( \Phi_{i+1} \) as

\[
\Phi_i = B^{-1} \Phi_{i+1} - B^{-1} \begin{bmatrix} \frac{1}{2} (r - \sigma^2) \phi(t_i, x_0) \Delta t \\ 0 \\ \vdots \\ 0 \\ -\frac{1}{2} (r(M - 1) + \sigma^2 (M - 1)^2) \phi(t_i, x_M) \Delta t \end{bmatrix},
\]

\( i = 0, 1, \ldots, N - 1 \), where the lateral boundary conditions \( \phi(t_i, x_0) \) and \( \phi(t_i, x_M) \) can be provided as in the case of the explicit scheme, allowing us to solve (17.7) recursively for \( \phi(t_{N-1}, x_j), \phi(t_{N-2}, x_j), \phi(t_{N-3}, x_j), \ldots \)

**Remark.** Note that for all \( j = 1, 2, \ldots, M - 1 \) we have

\[ B_{j,j-1} + B_{j,j} + B_{j,j+1} = 1 + r \Delta t, \]

hence when the terminal condition is a constant \( \phi(T, x) = c > 0 \) we get

\[ \phi(t_i, x) = c(1 + r \Delta t)^{-N-i} = c \left( 1 + r \frac{T}{N} \right)^{-N-i}, \quad i = 0, \ldots, N. \]

In particular, when the number \( N \) of discretization steps tends to infinity, denoting by \([x]\) the integer part of \( x \in \mathbb{R} \) we find

\[
\phi(s, x) = \lim_{N \to \infty} \phi(t_{[Ns/T]}, x) \\
= c \lim_{N \to \infty} \left( 1 + r \frac{T}{N} \right)^{-N-[Ns/T]} \\
= c \lim_{N \to \infty} \left( 1 + r \frac{T}{N} \right)^{-[N(T-s)/T]} \\
= c \lim_{N \to \infty} \left( 1 + r \frac{T}{N} \right)^{-(T-s)/T} \\
= c e^{-r(T-s)},
\]

for all \( s \in [0,T] \), as expected.
The implicit finite difference method is known to be more stable than the explicit scheme, as illustrated in Figure 17.2, in which the discretization parameters have been taken to be the same as in Figure 17.1.

\[ \text{Fig. 17.2: Stability of the implicit finite difference method.} \]

### 17.3 Euler Discretization

In order to apply the Monte Carlo method in option pricing, we need to generate a sequence \((\hat{X}_1, \ldots, \hat{X}_N)\) of sample values of a random variable \(X\), such that the empirical mean

\[
\mathbb{E}[\phi(X)] \simeq \frac{\phi(\hat{X}_1) + \cdots + \phi(\hat{X}_N)}{N}
\]

can be used according to the strong law of large number for the evaluation of the expected value \(\mathbb{E}[\phi(X)]\). Despite its apparent simplicity, the Monte Carlo method can converge slowly. The optimization of Monte Carlo algorithms and of random number generators have been the object of numerous studies which are outside the scope of this text, cf. e.g. Glasserman (2004), Korn et al. (2010).

Random samples for the solution of a stochastic differential equation of the form

\[
dX_t = b(X_t)dt + a(X_t)dW_t
\]

(17.8)
can be generated by discretization. More precisely, the Euler discretization scheme for the stochastic differential equation (17.8) is given by

\[
\hat{X}_{t_{k+1}}^N = \hat{X}_{t_k}^N + \int_{t_k}^{t_{k+1}} b(X_s)ds + \int_{t_k}^{t_{k+1}} a(X_s)dW_s
\]

\[
\simeq \hat{X}_{t_k}^N + b(\hat{X}_{t_k}^N)(t_{k+1} - t_k) + a(\hat{X}_{t_k}^N)(W_{t_{k+1}} - W_{t_k}),
\]
where \( W_{t_{k+1}} - W_{t_k} \simeq \mathcal{N}(0, t_{k+1} - W_{t_k}), \ k = 0, 1, \ldots, N - 1. \)

In particular, when \( X_t \) is the geometric Brownian motion given by

\[
dX_t = rX_tdt + \sigma X_t dW_t
\]

we get

\[
\hat{X}_{t_{k+1}}^N = \hat{X}_{t_k}^N + r\hat{X}_{t_k}^N(t_{k+1} - t_k) + \sigma\hat{X}_{t_k}^N(W_{t_{k+1}} - W_{t_k}),
\]

which can be computed as

\[
\hat{X}_{t_k}^N = \hat{X}_{t_0}^N \prod_{i=1}^{k} \left(1 + r(t_i - t_{i-1}) + \sigma(W_{t_i} - W_{t_{i-1}})\right), \ k = 0, 1, \ldots, N.
\]

### 17.4 Milshtein Discretization

In the Milshtein scheme we use (17.8) to expand \( a(X_s) \) as

\[
a(X_s) \simeq a(X_{t_k}) + a'(X_{t_k})(X_s - X_{t_k})
\]

\[
\simeq a(X_{t_k}) + a'(X_{t_k})(b(X_{t_k})(s - t_k) + a(X_{t_k})(W_s - W_{t_k}))
\]

\( 0 \leq t_k < s. \) As a consequence, we get

\[
\hat{X}_{t_{k+1}}^N = \hat{X}_{t_k}^N + \int_{t_k}^{t_{k+1}} b(X_s)ds + \int_{t_k}^{t_{k+1}} a(X_s)dW_s
\]

\[
\simeq \hat{X}_{t_k}^N + \int_{t_k}^{t_{k+1}} b(X_s)ds + a(X_{t_k})(W_{t_{k+1}} - W_{t_k})
\]

\[
+ a'(X_{t_k})b(X_{t_k}) \int_{t_k}^{t_{k+1}} (s - t_k)dW_s
\]

\[
+ a'(X_{t_k})a(X_{t_k}) \int_{t_k}^{t_{k+1}} (W_s - W_{t_k})dW_s
\]

\[
\simeq \hat{X}_{t_k}^N + \int_{t_k}^{t_{k+1}} b(X_s)ds + a(X_{t_k})(W_{t_{k+1}} - W_{t_k})
\]

\[
+ a'(X_{t_k})a(X_{t_k}) \int_{t_k}^{t_{k+1}} (W_s - W_{t_k})dW_s,
\]

Next, using Itô’s formula we note that

\[
(W_{t_{k+1}} - W_{t_k})^2 = 2 \int_{t_k}^{t_{k+1}} (W_s - W_{t_k})dW_s + \int_{t_k}^{t_{k+1}} ds,
\]

hence

\[
\int_{t_k}^{t_{k+1}} (W_s - W_{t_k})dW_s = \frac{1}{2}((W_{t_{k+1}} - W_{t_k})^2 - (t_{k+1} - t_k)),
\]
and
\[
\hat{X}_{tk+1}^N \simeq \hat{X}_{tk}^N + \int_{tk}^{tk+1} b(X_s)ds + a(X_{tk})(W_{tk+1} - W_{tk}) \\
+ \frac{1}{2} a'(X_{tk}) a(X_{tk}) ((W_{tk+1} - W_{tk})^2 - (tk+1 - tk))
\]
\[
\simeq \hat{X}_{tk}^N + b(X_{tk})(tk+1 - tk) + a(X_{tk})(W_{tk+1} - W_{tk}) \\
+ \frac{1}{2} a'(X_{tk}) a(X_{tk}) ((W_{tk+1} - W_{tk})^2 - (tk+1 - tk)).
\]

As a consequence the Milstein scheme is written as
\[
\hat{X}_{tk+1}^N \simeq \hat{X}_{tk}^N + b(\hat{X}_{tk}^N)(tk+1 - tk) + a(\hat{X}_{tk}^N)(W_{tk+1} - W_{tk}) \\
+ \frac{1}{2} a'(\hat{X}_{tk}^N) a(\hat{X}_{tk}^N) ((W_{tk+1} - W_{tk})^2 - (tk+1 - tk)),
\]
i.e. in the Milstein scheme we take into account the “small” difference
\[
(W_{tk+1} - W_{tk})^2 - (tk+1 - tk)
\]
existing between $(\Delta W_t)^2$ and $\Delta t$. Taking $(\Delta W_t)^2$ equal to $\Delta t$ brings us back
to the Euler scheme.

When $X_t$ is the geometric Brownian motion given by
\[
dX_t = rX_t dt + \sigma X_t dW_t
\]
we get
\[
\hat{X}_{tk+1}^N = \hat{X}_{tk}^N + (r - \sigma^2/2)\hat{X}_{tk}^N (tk+1 - tk) + \sigma \hat{X}_{tk}^N (W_{tk+1} - W_{tk}) \\
+ \frac{1}{2} \sigma^2 \hat{X}_{tk}^N (W_{tk+1} - W_{tk})^2,
\]
which can be computed as
\[
\hat{X}_{tk}^N = \hat{X}_{t0}^N \prod_{i=1}^{k} \left(1 + (r - \sigma^2/2)(ti - ti-1) + \sigma (W_{ti} - W_{ti-1}) + \frac{1}{2} \sigma^2 (W_{ti} - W_{ti-1})^2 \right).
\]
